Slackers – Client project 1 Report Section

Role & Responsibilities

Within the Slackers project, my role was primarily within the art and asset pipeline. Across the I was responsible for concept art 3D environmental modelling, character modelling and texturing, rigging the player and NPC characters, UI design, and 2D minigame assets. While the team was divided into those handling game mechanics and coding in unity and those responsible for the visual assets, I was the primary contributor on the art side, delivering assets that the coding team then integrated into the engine. This required me to manage my own workload independently while remaining communitive with the wider team, ensuring handoffs happened at the right times. For example, completing the level layout before the coders needed spatial references for the NPC movement, and finishing rigging character models before animations could be assigned. To manage this, I created a personal timeline (see Figure 1) which I used throughout the project to pace myself and my workload and to track deadlines relative to the team's needs.

Figure 1: My TimeLine

Interpreting the Client Brief

Upon receiving the client brief, my first task was to critically analyse the requirements and convert them into a clear set of priorities for myself and my group. The brief described a game in which players are aliens disguised as temporary workers, tasked with sabotaging a workplace without being caught, with an emphasis on a funny and chaotic tone. Rather than working from the brief wholesale, I broke it down into six key categories: The core player's objectives, tone, game play loop, success criteria, creative freedom, and environment (see Figure 2). This analysis allowed me and my group to have structured conversations rather than a vague creative discussion.

Figure 2: Whiteboard Idea Photos

During the initial brainstorming phase, the group identified six possible workplace settings, including a restaurant, retail shop, school, and a 999 dispatch office. We evaluated each against the client's requirements for a small, polished, and testable prototype. The tech support office was chosen because it offered a richer range of interactive props such as computers, cables, and photocopiers. And this provided us with a better contained spatial layout suitable for a small team to deliver within our timeframe, and a strong comedic potential given the briefs chaotic tone.

With the setting agreed, I moved into creating the concept art for the level layout (see Figure 3 and Figure 4), producing both a base floor plan and a colour annotated version with asset labels. I did this deliberately so that the team had a shared visual reference and to prevent any miscommunication about the spatial layout and give the coders a concrete map to work from when scripting NPC patrol routes. This approach of producing annotated concept documentation before beginning 3D work reflects good pre-production practice, ensuring implementation is guided by a clear plan rather than being an ad hoc decision during asset creation.

Iterations & Feedback

A recurring theme across this project was iterating based on feedback both from my teammates and from informal peer testing. This process shaped almost every significant asset I produced.

Player Character: My first alien concept designs were conventional with typical extraterrestrial shapes that, when shown to peers, were described as too stereotypical and insufficiently suited to the comedic tone of the game (see Figure 5). Taking this feedback seriously, I returned to the design and introduced the cardboard box disguise design concept of an alien hiding inside a cardboard box with a crudely drawn face on the front, wearing a marker drawn tie. This redesign (see Figure 6) was received considerably more positively by both the team and external

reviewers, who agreed it matched the chaotic, self-aware humour of the brief. I extended this further by adding a tape texture effect after further feedback suggested the cardboard appearance could be reinforced with additional visual details. I created this tape texture using IbisPaint exported it as a transparent PNG and layered it onto the model using blender's texture node system ('Shader Editor - Blender Manual', n.d.) (see Figure 7). Correcting the UV mapping to ensure the texture sat correctly on each part of the model was a key technical challenge at this stage (see Figure 8 and Figure 9).

Figure 5: First alien concepts

Figure 6: Revised alien concept

Figure 7: Tape effect on model

Figure 8: Before UV correction

Figure 9: After UV correction

NPC Designs: The NPC characters were modelled with a Funko Pop inspired aesthetic agreed upon with the group. I produced three face styles, three clothing variants, and six hairstyles to create visible variety between the characters. However, when I showed the initial textured NPCs to the team, feedback indicated that having identical sized facial features across all four NPCs made them feel too uniform and lacking individuality (see Figure 10). To resolve this, I adjusted the UV mapping of each NPC's faces independently, which was the process that involved repositioning and rescaling the 2D representation of the 3D mesh surface so that textures sit correctly on the model ('UV Mapping — Blender Manual', n.d.), altering the scale and positioning of the eye and eyebrow textures to give each character a distinct expression. The revised designs (see Figure 11) were much better received with the team agreeing they added more personality and improved immersion.

Figure 11: Old NPC faces

Figure 10: New NPC faces

UI Design: My initial concept design for the main menu featured the games working aesthetic and a cardboard textured background with a paper CV as the menu panel. After sharing this with the group, I received feedback to improve the layout clarity, use a more legible font, and add segmented navigation such as solo/multiplayer, settings, and quit buttons, and to bring the design closer to a recognizable CV format. I implemented all these changes (see Figure 12), and the revised design was signed off by the group. For the pause menu, I kept the feedback given to me from the menu design in mind and introduced a sticky note design with hand drawn doodle details, chosen to maintain thematic consistency while differentiating from the main menu.

Teamwork & Delivery

Effective team work on Slackers required clear communication between the art and the development side of the team, particularly because the work was highly sequential as the coders couldn't finalise the NPC movement patterns without knowing the level layout and couldn't integrate the characters without receiving properly formatted exports. I was mindful of these

dependencies from the outset, which is why I prioritised producing the level concept art early and completing the level assets before moving to the characters.

When exporting assets to Unity, I ensured all models were correctly UV mapped, and textures were baked into PNGs, and that files were exported in FBX format and imported into Unity (Unity Technologies, 2024). This process is necessary because Blender's internal materials and texture nodes are not directly compatible with Unity's rendering pipeline, meaning textures must be baked to image files before exporting so they display correctly once imported ('Render Baking - Blender 4.3 Manual', 2024). I then created new materials within Unity for each asset and attached the baked textures accordingly (see Figure 13, Figure 14, and Figure 15). UI assets were delivered as separate transparent PNGs to allow the coders full flexibility in implementing them into the game.

Figure 14: NPCs in Unity

Group decisions were made collaboratively either in person or by keeping contact through a group chat on social media. The choice to cap the NPC count at four was a joint decision I contributed to, reasoning that a larger number of characters would crowd the level and dilute the players' focus. Similarly, the choice of a tech support office setting and the co-op gameplay direction emerged from our frequent discussions. Disagreements were resolved by circling back to the client briefs success criteria, particularly the emphasis on a clear gameplay loop and a polished testable prototype.

Value, Responsibility & SDG 8

Sustainable development goal 8 focuses on promoting sustainable inclusive economic growth and decent work for all (United Nations, 2025). While a student game prototype may appear disconnected from this goal, the Slackers project connects to SDG 8 on multiple levels.

The games industry is one of the fastest growing creative sectors globally, and developing professional skills such as asset pipelines, cross discipline collaboration, and client facing deliverables, directly prepares students for employment within that industry. The client project model simulates real industry conditions like having a brief, a deadline, a team, and external expectations. Working within these conditions helps students develop practical and transferable

skills that will contribute towards building a skilled and adaptable workforce that sustained economic growth depends upon (United Nations, 2025).

On a personal level, this project required me to manage my own workload, communicate professionally across disciplines, and deliver to a client standard, all of which are skills directly relevant to entering the creative industry as a paid professional. SDG 8 emphasises not just existence of jobs, but the quality and inclusivity of employment (United Nations, 2025).

Participating in a project that mirrors real studio workflows help bridge the gap between education and the type of decent, skilled employment SDG 8 advocates for.

Additionally, *Slackers* itself carries implicit commentary on workplace culture. With the premise of temporary workers, in this case aliens in disguise, sabotaging corporate environments, it playfully critiques precarious employment and the absurdity of performative productivity. While humorous in tone, games that engage with workplace themes contribute to the wider cultural conversations about labour conditions and worker wellbeing, these areas are ones that sit at the base of SDG 8's vision of dignified and compensated employment for all (United Nations, 2025)

The UK games industry is one of the country's most significant creative employers, contributing over £7 billion to the economy and supporting tens of thousands of jobs ('The games industry in numbers | Ukie', 2018). Developing industry standard skills such as Blender modelling, Unity asset pipelines, cross discipline collaboration, and a client project directly feeds into this ecosystem. The client project model is therefore not just an academic exercise, but a preparation for participation in a sector that SDG 8 would recognise as a meaningful contributor to sustained economic growth

Role & Responsibilities

My agreed role for this client project was to focus exclusively on the enemy for the game, this included the designing, modelling, rigging, and animating the enemy so that the coding team could easily implement it into Unity as a functioning AI entity. This was a role I felt well prepared for having spent term 1 rigging and animating characters for Slackers, meaning I could hit the ground running with the enemy model from the first week. The project was a horror prototype built around a fast paced, unkillable monster, and as such the enemy was arguably the most important asset in the entire game. My responsibilities for this asset also covered the enemy concept art, 3D sculpting, UV mapping, texture painting, rigging, weight painting, and animation planning.

However, by week nine of the twelve week project, it became clear that several teammates had fallen significantly behind on their assigned roles. The level had no assets, and there was no environment for the coder to build within. Faced with this, I made the decision to step up and take on the level design assets in addition to my existing enemy work. This meant I was responsible for the complete visual output of the project, including all the environment assets across every room of the oil rig level, the wall and hallway system, the block outs of the layout, and the enemy model in its entirety. To accommodate this new larger workload and the

remaining time available, I made the deliberate artistic decision to lower the overall poly count and visual detail of the game, shifting to a low poly aesthetic that allowed assets to be produced at a speed without sacrificing consistency. I had created a project timeline at the start of the project (see Figure 16) to keep the group on track, though ultimately, I was the primary contributor who adhered to it.

Figure 16: Timeline from Miro board

Interpreting the Client Brief

Upon receiving the client brief, I applied the same analytical approach I had developed during the Slackers project in Term 1. Rather than treating the brief as a single block of text, I broke it down into six clearly defined categories, these being: project goals, the core game play loop, the success criteria, core learning, the scope, and the creative freedom (See figure 17). This structured breakdown made it easier for the team to have focused conversations and ensured that every design decision I made could be traced back to a specific brief requirement.

The brief's core requirements were clear: one unkillable enemy, one small level, no combat, and a focus on tension, evasion, and player knowledge. The creative freedom section gave us latitude on the setting and monster design, which the team used during brainstorming to develop our oil rig concept. The story we settled on was that the player would be with a group of scavengers exploring an abandoned oil rig, losing their crew, and being hunted by an unknown entity. This fulfilled the brief's atmosphere requirements while offering a strong visual identity for the enemy and level.

Researching different games to reference was an important part of creating and influencing our design decisions. I looked at Monstrum ('Monstrum', 2015), which shares the concept of being trapped in an isolated environment while being hunted, and Alien: Isolation ('Alien: Isolation', 2014), specifically for how it uses audio cues to signal enemy proximity, which is a mechanic directly relevant to our brief's emphasis on tension and readability. I also referenced Iron Lung ('Iron Lung', 2022) later in the project as a low poly visual reference when we needed to reduce asset detail. These were not passive references as each informed a specific design choice. Alien: Isolation, for example, influenced my decision to design the enemy with distinctive silhouette features, I did this with an exposed ribcage and tentacle clusters so the player could read its presence in low light (see Figure 18, Figure 19, and Figure 20).

Figure 20: Final rendered concept sketch of enemy

Iterations & Feedback

Following the process of Slackers in term 1, I received a large amount of feedback on my work which helped to massively improve the pipeline and creation of the characters and assets for the final design of the game. In response to this, I made the conscious decision to actively seek feedback whenever I could when I approached the Oil Rig game.

Specifically, feedback to help improve the visuals designs and artistic approach to my work, as pervious feedback helped me create a better player character and provide a more communally liked character which players enjoyed the style and aesthetics of.

Iterations were central to every significant output I produced across this project, and the feedback loop operated at multiple levels, with peer reviews within the team, self-critique during production, and practical problem solving when technical issues arose.

Enemy Concept and Design: My initial concept sketch of the enemy was a rough working idea rather than a finished design. This concept included a tall, emaciated figure with an exposed ribcage, long hair, and tentacle clusters at the arms and torso (see Figure 19). When I presented

this to the group, the responses were positive and the design was agreed upon unanimously, which gave me confidence to invest time in refining it. I produced a more detailed final rendered sketch (see Figure 20) that mapped out how the character would move, how the hair and tentacles would behave, and where the main visual focus points sat. I also produced animation concept sketches (see Figure 21) converging idle, walking, running, and a player death states. This isn't because I knew the animations would survive the final build of the game, but because planning movement early would help inform how the enemy would move when animating and rigging the model.

Enemy Modelling and Rigging: I began the body by shaping a base mesh into a rough torso form and sculpting it, working in a T-pose as standard practice to simplify rigging ('Armatures — Blender Manual', 2024). For the ribcage, I used Bezier curves and metaballs rather than polygon modelling, as these tools gave me faster and more organic results for curved skeletal shapes. My first rib model was too wide and sat incorrectly against the body (see Figure 22), so I brought the lower ribs inwards to achieve a more anatomically believable shape (see Figure 23). This kind of self directed iteration with noticing problems, identifying its cause, and fixing them was something I applied consistently throughout the modelling process.

When I added the armature and applied automatic weights, the ribcage bones clipped through the mesh in an unnatural way. Automatic weighting works well for standard humanoid meshes but struggles with complex or non-standard geometry ('Weight Paint - Blender 4.1 Manual', 2024). To fix this, I manually weight painted the ribcage and tentacle areas, giving me a more precise

control over how the mesh deformed during posing (see Figure 24). I also added two additional bones to the torso and one to the end of each arm specifically to control the tentacle movement without distortion.

Enemy Remodel and Poly Reduction: By week nine, the team's delays meant the projects' visual scope had to be reduced. I made the decision to use Blender's Decimate modifier to lower the enemy's poly count rather than rebuilding it from scratch (see Figure 25). This was a pragmatic decision that preserved the weeks of modelling work while aligning the enemy with the new low poly art direction. I then moved to texture painting directly on the model, adding blood stains bruising, and skin discolouration to retain visual detail through a painted surface rather than a geometric complexity (see Figure 26). This approach gave me more artistic control over the final look and ensured the enemy matched the simplified aesthetic of the level's assets.

Level Design Iteration: My first level layout was received with mixed feedback with several teammates felt it resembled too much of a maze and that players would struggle to navigate it under pressure (see Figure 27). Taking this on board, I went through multiple revised layouts before settling on a final design (see Figure 28) that the whole team agreed offered better spaced walkways, a more logical room arrangement, and a clear sightline. Once agreed upon, I annotated the layout with asset placements per room (see Figure 29) so that I could produce the asset collections systematically and the level designer had a clear reference when building in Unity.

Teamwork & Delivery

The Oil Rig project presented significantly greater teamwork challenges than Slackers, and reflecting on those challenges honestly is as important as documenting the work itself. I had created a shared timeline at the start of the project (see Figure 16) to ensure the group had a clear, collective sense of pacing. Despite this, by week nine several teammates had not delivered on their assigned tasks, leaving the project without level assets and insufficient time to produce them from scratch at the originally planned level of detail.

My response to this situation was to take on the outstanding work rather than wait for others to catch up. While this was the right decision for the project's delivery, it meant I was managing two full roles simultaneously in the final weeks, having to complete the enemy model and producing all level assets. To make this possible, I coordinated with the level designer directly and using the shared Miro board we collaboratively produce a room-by-room breakdown and an asset list (see Figure 30), agreeing which assets would be reused across multiple rooms and which were room specific. This collaboration was essential as without it I could have spent time on assets that were never needed or missed ones that were critical.

For the assets themselves, I developed a consistent low poly texture system using blender's snap (Vector math) node to produce a pixelated texture style (see Figure 31, and Figure 32). Using this as a base for every asset ensured a visual constancy across all rooms, even though the assets were produced rapidly. Room collections included hallways, laundry rooms, office, kitchen, electrical room, bedroom, and radio room, as well as a reusable furniture which included tables,

Value, Responsibility & SDG 8

Sustainable Development Goal 8 promotes sustained, inclusive economic growth and decent, productive work for all (United Nations, 2015). The Oil Rig project connects to this goal in ways that feel more direct than in Term 1, partly because of the challenges I faced.

Taking on a significantly expanded workload when teammates fell behind is not an unusual situation in the creative industries. Studios regularly face understaffing, scope creep, and shifting responsibilities. Navigating this and making pragmatic decisions about quality, scope, and time, while still delivering a functional prototype mirrors the kind of professional resilience that real employment in the games industry demands. SDG 8 recognises that inclusive economic growth depends not just on the number of jobs available, but on whether people within those roles have the skills and adaptability to respond to changing demands (United Nations, 2025). This project developed both of those capacities in my directly.

Additionally, the decision to shift to a low poly aesthetic in response to time constraints was not a compromise, it was a creative and economical problem-solving choice. The horror genre has a history of using visual restraints to amplify tension rather than diminish it, and low poly art has proven a commercially viable and critically respected aesthetic within independent game development. Making design choices that are both time efficient and artistically defensible reflects the type of thinking that contributes to sustainable creative production of doing more with less, without sacrificing the player's experience. This mirrors the spirit of SDG 8's emphasis on innovation as a driver of growth and decent work (United Nations, 2025).

This experience has reinforced my understanding that the creative industries, like any other sector, depends on individuals who can adapt, deliver under pressure, and continue developing their skills, all of which are central to SDG 8's vision of a sustained and inclusive economy.

Personal Reflection

Comparing my work across both projects, the most significant area of technical growth was in rigging and weight painting. In *Slackers*, I applied automatic weights to the plyer character and made minor manual adjustments. By the *Oil Rig* project, I was able to manually weight paint complex non-humanoid geometry, such as the tentacles, hair, and ribcage, from scratch. Which required a considerable deeper understanding of how Blender's weight system works ('Weight Paint - Blender 4.1 Manual', 2024). Beyond technical skills, my ability to manage a pipeline under pressure developed considerably. In term 1 I was managing my own workload within a functioning team. In term 2 I was effectively managing the entire art output of the project as my original role expanded unexpectedly. This shift required me to make rapid scope decisions, strictly reprioritise, and proactively communicate with the coder to ensure assets were delivered in the right format and order.

Reflecting critically on my own performance, one area I would approach differently is my communication, especially in term 2, when I first noticed teammates falling behind. Rather than absorbing the work independently from week nine onwards, raising the issue earlier, either within the group or with a lecturer, may have allowed for a more manageable redistribution of tasks. This is a professional lesson as much as an academic one, as in a studio environment,

flagging capacity issues early is considered a good practice because it protects the quality of the final delivery of the game.

Overall, together these two projects represent a significant leap in both my technical capability and my professional resilience, and I feel considerably more prepared for the industry as a result.
